Abstract

Ideals of continuous functions which satisfy an *off diagonality* condition proved to be important connected with the solution of large classes of nonlinear PDEs, and more recently, in General Relativity and Quantum Gravity. *Maximal ideals* within those which satisfy that off diagonality condition are important since they lead to differential algebras of generalized functions which can handle the largest classes of *singularities*. The problem of finding such maximal ideals satisfying the off diagonality condition is formulated within some background detail, and commented upon.

1. The Problem

As presented in section 4, there is a significant interest, both in Mathematics and Physics, to find out the structure of *maximal ideals* $\mathcal{I}$ in the algebra $(C(\mathbb{R}^n))^\Lambda$, among all those ideals which satisfy the *off diagonality* condition

\begin{equation}
\mathcal{I} \cap U_\Lambda(\mathbb{R}^n) = \{ 0 \}
\end{equation}

Let us clarify the above notation. First, $C(\mathbb{R}^n)$ is the set of all real valued continuous functions on $\mathbb{R}^n$, while $\Lambda$ is an arbitrary infinite set. Consequently, $(C(\mathbb{R}^n))^\Lambda$ is the Cartesian product of $\Lambda$ copies of $C(\mathbb{R}^n)$, thus it can be identified with $C(\Lambda \times \mathbb{R}^n)$, that is, with the set of real valued continuous functions on $\Lambda \times \mathbb{R}^n$, where $\Lambda$ is taken with the discrete topology. Clearly, $(C(\mathbb{R}^n))^\Lambda$ is a commutative unital algebra over $\mathbb{R}$, and we have the algebra embedding

\begin{equation}
C(\mathbb{R}^n) \ni \psi \mapsto u(\psi) \in (C(\mathbb{R}^n))^\Lambda
\end{equation}

where $u(\psi) = (\psi_\lambda | \lambda \in \Lambda)$, with $\psi_\lambda = \psi$, for $\lambda \in \Lambda$. In this way, the unit element in $(C(\mathbb{R}^n))^\Lambda$ is $u(1)$, where $1 \in C(\mathbb{R}^n)$ denotes the constant function with value 1 defined on $\mathbb{R}^n$. Finally, $U_\Lambda(\mathbb{R}^n)$ denotes the image of $C(\mathbb{R}^n)$ in $(C(\mathbb{R}^n))^\Lambda$ through the algebra embedding (1.2), thus

\begin{equation}
U_\Lambda(\mathbb{R}^n) = \{ u(\psi) | \psi \in C(\mathbb{R}^n) \}
\end{equation}

---

\( ^1 \) Correspondence: Elemér E Rosinger Address: Department of Mathematics and Applied Mathematics, University of Pretoria, Pretoria, 0002 South Africa. Email: eerosinger@hotmail.com
is a subalgebra in \((C(R^n))^\Lambda\), and through (1.2), it is isomorphic with \(C(R^n)\).

With the above, the meaning of (1.1) becomes clear, recalling that \(\{0\}\) in its right hand term denotes the trivial zero ideal in \((C(R^n))^\Lambda\).

In this way \(U_\Lambda(R^n)\) is in fact the diagonal in the Cartesian product \((C(R^n))^\Lambda\). Thus (1.1) is indeed an off diagonality condition on the respective ideals \(I\) in \((C(R^n))^\Lambda\).

As seen in the sequel, the interest in maximal ideals satisfying the off diagonality condition (1.1) comes from the fact that such ideals lead to the effective construction of differential algebras of generalized functions which can handle the largest classes of singularities.

Before going further, let us briefly point to the mathematical nontriviality of the problem in (1.1). Indeed, as mentioned, \((C(R^n))^\Lambda\) can be identified with \(C(\Lambda \times R^n)\), thus as is well known, Gillman & Jerison, the problem of the structure of maximal ideals \(I\) in \((C(R^n))^\Lambda\) is closely related to the Stone-Čech compactification \(\beta(\Lambda \times R^n)\) of \(\Lambda \times R^n\), which in itself is a rather involved problem even in the simplest case of interest above, namely, when \(\Lambda = \mathbb{N}\). One of the reasons which makes \(\beta(\Lambda \times R^n)\) not easy to deal with is that, in general, for two completely regular topological spaces \(X\) and \(Y\), the spaces \(\beta(X \times Y)\) and \(\beta X \times \beta Y\) are different. Furthermore, the space \(\beta \mathbb{N}\) alone is known to be highly nontrivial.

On the other hand, in (1.1), one asks the yet more difficult problem of finding the maximal ideals \(I\) in \((C(R^n))^\Lambda\) which satisfy the respective additional condition, thus they can no longer be maximal in \((C(R^n))^\Lambda\). Therefore, their structure is quite likely still more complex, Gillman & Jerison.

2. Some Examples of Large Off Diagonal Ideals

As is well known, Gillman & Jerison, the structure of maximal ideals \(I\) in the algebra \(C(X)\) of real valued continuous functions on a completely regular topological space \(X\) is closely related to certain vanishing conditions satisfied by the functions \(f \in I\). Indeed, in the case \(X\) is compact, for instance, then the maximal ideals \(I\) in \(C(X)\) are given by the family of ideals

\[
M_p = \{ f \in C(X) \mid f(p) = 0 \}, \quad \text{with } p \in X
\]

In general, when \(X\) is not compact, as for instance happens in our case with \(X = \Lambda \times R^n\), the vanishing condition characterizing the functions in a maximal ideal is connected with the Stone-Čech compactification \(\beta X\) of \(X\). Namely, the maximal ideals \(I\) in \(C(X)\) are given by the family of ideals

\[
M^p = \{ f \in C(X) \mid p \in cl_{\beta X} Z(f) \}, \quad \text{with } p \in \beta X
\]

where \(Z(f) = \{ x \in X \mid f(x) = 0 \}\) is the zero set of \(f\), and \(cl_{\beta X}\) denotes the closure operation in the topology of \(\beta X\).
In view of the above, we are interested in the case when \( X = \Lambda \times \mathbb{R}^n \), and it is obvious that the ideals \( \mathcal{I} \) in \( (C(\mathbb{R}^n))^\Lambda \) which satisfy the off diagonality condition (1.1) must satisfy \textit{stronger vanishing} conditions than those in (2.2), since in view of (1.1), such ideals are significantly smaller than the maximal ideals in \( C(\Lambda \times \mathbb{R}^n) \). Consequently, by looking for such maximal ideals among the ideals satisfying the off diagonality condition (1.1), we are looking for the \textit{weakest} vanishing conditions satisfied by such ideals. And as seen later, this corresponds to the \textit{largest} families of singularities which the corresponding differential algebras of generalized functions can handle.

A first instance of such stronger vanishing conditions were introduced and used connected with the so called \textit{nowhere dense} ideals, Rosinger [1-19], Mallios & Rosinger [1-3], Mallios [1,2], Rosinger & Walus [1,2], upon which differential algebras of generalized functions were constructed with the initial aim to solve large classes of non-linear partial differential equations. Later, such algebras proved to have a special interest in a variety of basic theories in Physics, among them General Relativity and Quantum Gravity, Mallios [2].

These nowhere dense ideals are defined as follows. Let \( \Lambda = \mathbb{N} \), and let us denote by \( \mathcal{I}_{nd}(\mathbb{R}^n) \) the ideal whose elements are all the sequences \( w = (w_0, w_1, w_2, \ldots) \in (C(\mathbb{R}^n))^\mathbb{N} \) of real valued continuous functions \( w_\nu \) which satisfy the \textit{asymptotic vanishing} condition

\[
\exists \; \Gamma \subset \mathbb{R}^n, \; \text{closed, nowhere dense :}
\]

\[
\forall \; x \in \mathbb{R}^n \setminus \Gamma :
\]

\[
(2.3) \; \exists \; \mu \in \mathbb{N} :
\]

\[
\forall \; \nu \in \mathbb{N}, \; \nu \geq \mu :
\]

\[
w_\nu(x) = 0
\]

In this case the off diagonality condition (1.1), namely

\[
(2.4) \; \mathcal{I}_{nd}(\mathbb{R}^n) \cap \mathcal{U}_N(\mathbb{R}^n) = \{ 0 \}
\]

follows immediately from the fact that the subsets \( \mathbb{R}^n \setminus \Gamma \) are always \textit{dense} in \( \mathbb{R}^n \), thus a continuous function \( \psi \in C(\mathbb{R}^n) \) which vanishes on such a subset must vanish on the whole of \( \mathbb{R}^n \).

Indeed, let \( w = (w_0, w_1, w_2, \ldots) \in \mathcal{I} \cap \mathcal{U}_N(\mathbb{R}^n) \), then in view of (1.3), there exists \( \psi \in C(\mathbb{R}^n) \), such that \( w = u(\psi) \), therefore \( w_\nu = \psi \), for \( \nu \in \mathbb{N} \). And then (2.3) clearly implies that, for a suitable closed and nowhere dense \( \Gamma \subset \mathbb{R}^n \), we have \( \psi = 0 \) on \( \mathbb{R}^n \setminus \Gamma \). Therefore, the continuity of \( \psi \) will imply that \( \psi = 0 \) on the whole of \( \mathbb{R}^n \).

The meaning of the vanishing condition (2.3) is that the sequences of continuous functions \( w = (w_\nu | \nu \in \mathbb{N}) \) in the ideal \( \mathcal{I}_{nd}(\mathbb{R}^n) \) may cover with their support the
singularity set $\Gamma$, while at the same time, they vanish asymptotically outside of it, that is, on $\mathbb{R}^n \setminus \Gamma$.

In this way, the ideal $\mathcal{I}_{nd}(\mathbb{R}^n)$ carries in an algebraic manner the information on all the respective sets $\Gamma$ which are sets of singularities of generalized functions. And one should recall that such closed and nowhere dense sets $\Gamma$ can have arbitrary large positive Lebesgue measure, Oxtoby.

In view of (2.3), it follows that the sequences of continuous functions in the nowhere dense ideals $\mathcal{I}_{nd}(\mathbb{R}^n)$ satisfy an asymptotic vanishing condition on corresponding open, dense subsets of $\mathbb{R}^n$, a condition which is obviously much stronger than the vanishing conditions in (2.1) or (2.2).

As it turned out, however, the nowhere dense ideals $\mathcal{I}_{nd}(\mathbb{R}^n)$ were far from being maximal within the ideals in $(\mathcal{C}(\mathbb{R}^n))^N$ which satisfy the off diagonality condition (1.1). Indeed, in Rosinger [12-16], the following far larger class of such ideals were introduced and used, see for applications Mallios & Rosinger [2,3] and Mallios [2].

Let us consider various families of singularities in $\mathbb{R}^n$, each such family being given by a corresponding set $\mathcal{S}$ of subsets $\Sigma \subset \mathbb{R}^n$, with each such subset $\Sigma$ describing a possible set of singularities of a certain given generalized function.

The largest family of singularities $\Sigma \subset \mathbb{R}^n$ which we can consider so far is given by

\begin{equation}
S_D(\mathbb{R}^n) = \{ \Sigma \subset \mathbb{R}^n \mid \mathbb{R}^n \setminus \Sigma \text{ is dense in } \mathbb{R}^n \}
\end{equation}

And to get an idea how large such singularity sets $\Sigma$ can be, let us note that in the one dimensional case of $\mathbb{R}$, if we take $\Sigma$ as the set of all irrational numbers, then clearly $\Sigma \in S_D(\mathbb{R})$, since $\mathbb{R} \setminus \Sigma$ is the set of rational numbers, thus it is dense in $\mathbb{R}$. In this way, it can happen that a given set $\Sigma$ of singularities has a larger cardinal than its complement, that is, than the set of non-singular points.

The various families $\mathcal{S}$ of singularities $\Sigma \subset \mathbb{R}^n$ which we shall deal with will each satisfy the condition $\mathcal{S} \subseteq S_D(\mathbb{R}^n)$.

Examples of two such families of interest are the following

\begin{equation}
S_{nd}(\mathbb{R}^n) = \{ \Sigma \subset \mathbb{R}^n \mid \Sigma \text{ closed, nowhere dense in } \mathbb{R}^n \}
\end{equation}

and

\begin{equation}
S_{\text{Baire I}}(\mathbb{R}^n) = \{ \Sigma \subset \mathbb{R}^n \mid \Sigma \text{ is of first Baire category in } \mathbb{R}^n \}
\end{equation}

Obviously

\begin{equation}
S_{nd}(\mathbb{R}^n) \subset S_{\text{Baire I}}(\mathbb{R}^n) \subset S_D(\mathbb{R}^n)
\end{equation}

And now to the definition of the so called space-time foam ideals with dense sin-
gularities, introduced in Rosinger [12-16].

First, let us take any family \( S \) of singularity sets \( \Sigma \subset \mathbb{R}^n \), family which satisfies the following two conditions

\[
\forall \Sigma \in S : \quad \mathbb{R}^n \setminus \Sigma \text{ is dense in } \mathbb{R}^n
\]

(2.9)

and

\[
\forall \Sigma, \Sigma' \in S : \quad \exists \Sigma'' \in S : \quad \Sigma \cup \Sigma' \subseteq \Sigma''
\]

(2.10)

Clearly, we shall have the inclusion \( S \subseteq S_D(\mathbb{R}^n) \) for any such family \( S \).

It is easy to see that both families \( S_{nd}(\mathbb{R}^n) \) and \( S_{Baire}(\mathbb{R}^n) \) satisfy conditions the (2.9) and (2.10). On the other hand, the family \( S_D(\mathbb{R}^n) \) as a whole does not satisfy condition (2.10). Indeed, one can partition \( \mathbb{R}^n \) into two subsets \( \Sigma \) and \( \Sigma' \), both of which are dense in \( \mathbb{R}^n \), thus both belong to \( S_D(\mathbb{R}^n) \). In this case, in (2.10), we would have to have \( \Sigma'' = \mathbb{R}^n \), which obviously does not belong to \( S_D(\mathbb{R}^n) \).

Now, as the second ingredient, and so far independently of any \( S \) above, we take any right directed partial order \( L = (\Lambda, \leq) \). In other words, \( L \) is such that for each \( \lambda, \lambda' \in \Lambda \) there exists \( \lambda'' \in \Lambda \) with \( \lambda, \lambda' \leq \lambda'' \). Here we note that the choice of \( L \) may at first appear to be completely independent of \( S \), yet in certain specific instances the two may be somewhat related, with the effect that \( \Lambda \) may have to be large, see Rosinger [15].

Although we shall only be interested in singularity sets \( \Sigma \in S_D(\mathbb{R}^n) \), the following ideal can in fact be defined for any \( \Sigma \subseteq \mathbb{R}^n \). Indeed, let us denote by

\[
J_L, \Sigma(\mathbb{R}^n)
\]

the ideal in \((C(\mathbb{R}^n))^\Lambda\) of all the sequences of continuous functions indexed by \( \lambda \in \Lambda \), namely, \( w = (w_\lambda | \lambda \in \Lambda) \in (C(\mathbb{R}^n))^\Lambda \), sequences which outside of the singularity set \( \Sigma \) will satisfy the asymptotic vanishing condition

\[
\forall x \in \mathbb{R}^n \setminus \Sigma : \quad \exists \lambda \in \Lambda : \quad \forall \mu \in \Lambda, \mu \geq \lambda : \quad w_\mu(x) = 0
\]

(2.12)
This means that the sequences of continuous functions \( w = ( w_\lambda | \lambda \in \Lambda ) \) in the ideal \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \) may cover with their support the singularity set \( \Sigma \), and at the same time, they vanish asymptotically outside of it, that is, on \( \mathbb{R}^n \setminus \Gamma \).

In this way, the ideal \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \) carries in an algebraic manner the information on the singularity set \( \Sigma \).

Here however, with the ideals \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \), the asymptotic vanishing happens on \( \mathbb{R}^n \setminus \Sigma \). And as seen below, we shall only require that such sets \( \mathbb{R}^n \setminus \Sigma \) be dense in \( \mathbb{R}^n \), in other words that \( \Sigma \in S_D(\mathbb{R}^n) \). Thus the corresponding vanishing conditions are significantly weaker than that required in the case of the nowhere dense ideals \( \mathcal{I}_{nd}(\mathbb{R}^n) \).

In follows that the nowhere dense ideals only allow singularities on closed and nowhere dense subsets \( \Gamma \subset \mathbb{R}^n \), whose complementaries \( \mathbb{R}^n \setminus \Gamma \) are therefore open and dense in \( \mathbb{R}^n \). On the other hand, the case of the ideals \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \) in which we shall be interested, namely when \( \Sigma \in S_D(\mathbb{R}^n) \), allow arbitrary and much larger singularities \( \Sigma \subset \mathbb{R}^n \), as long their complementaries \( \mathbb{R}^n \setminus \Sigma \) are still dense in \( \mathbb{R}^n \).

We note that the assumption about \( L = (\Lambda, \leq) \) being right directed is used in proving that \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \) is indeed an ideal, more precisely that, for \( w, w' \in \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \), we have \( w + w' \in \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \).

Now, it is easy to see that for \( \Sigma, \Sigma' \subset \mathbb{R}^n \) we have

\[ \Sigma \subseteq \Sigma' \implies \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \subseteq \mathcal{J}_{L, \Sigma'}(\mathbb{R}^n) \]

In this way, for any family \( S \) of singularity sets \( \Sigma \subset \mathbb{R}^n \) satisfying (2.9), (2.10), it follows that

\[ \mathcal{J}_{L, S}(\mathbb{R}^n) = \bigcup_{\Sigma \in S} \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \]

is also an ideal in \( (C(\mathbb{R}^n))^\Lambda \).

It is important to note that for suitable choices of the right directed partial orders \( L \), the ideals \( \mathcal{J}_{L, \Sigma}(\mathbb{R}^n) \), with \( \Sigma \in S_D(\mathbb{R}^n) \), are nontrivial, that is, they do not reduce to the zero ideal \( \{0\} \), Rosinger [15, section 2]. Thus in view of (2.14), the same will hold for the ideals \( \mathcal{J}_{L, S}(\mathbb{R}^n) \).

Let us conclude by showing that the ideals \( \mathcal{J}_{L, S}(\mathbb{R}^n) \) satisfy the off diagonality condition (1.1), namely

\[ \mathcal{J}_{L, S}(\mathbb{R}^n) \cap U_\Lambda(\mathbb{R}^n) = \{0\} \]

for every family \( S \) of singularities which satisfies (2.9) and (2.10). Indeed, let

\[ w = ( w_\lambda | \lambda \in \Lambda ) \in \mathcal{J}_{L, S}(\mathbb{R}^n) \cap U_\Lambda(\mathbb{R}^n) \]
then in view of (2.14), there exists $\Sigma \in S$, such that

$$w = (w_\lambda \mid \lambda \in \Lambda) \in J, \Sigma(\mathbb{R}^n)$$

On the other hand, we have $w = u(\psi)$, for a certain $\psi \in C(\mathbb{R}^n)$. Thus $w_\lambda = \psi$, for $\lambda \in \Lambda$. And then (2.12) implies that $\psi = 0$ on $\mathbb{R}^n \setminus \Sigma$, which means that $\psi = 0$ on the whole of $\mathbb{R}^n$, since $\mathbb{R}^n \setminus \Sigma$ is dense in $\mathbb{R}^n$, in view of (2.9).

3. Towards Finding the Maximal Ideals

Let $X$ be a completely regular topological space. The relations (2.1) and (2.2) indicate that important properties of the algebra $C(X)$ of real valued continuous functions on $X$ may be expressed in terms of the topology of $X$ or of $\beta X$. Such a translation of algebraic properties into topological ones, or vice versa, may often prove useful, and we shall mention some of them.

**Customary Notations and Facts.** We recall, Gillman & Jerison, the following notations. First

(3.1) $Z(X) = \{Z(f) \mid f \in C(X)\}$

is the set of all zero-sets of functions in $C(X)$. Each such $Z(f)$ is closed in $X$, since the respective $f$ are continuous. However, $Z(X)$ need not in general be the set of all closed subsets of $X$.

A family $F$ of zero-sets is called a $z$-filter on $X$, if and only if it satisfies the following conditions

(*) $\phi \notin F$

(3.2) (**$)$ $Z, Z' \in F \implies Z \cap Z' \in F$

(**$*$) $Z \in F, Z' \in Z(X), Z \subseteq Z' \implies Z' \in F$

For any ideal $I$ in the algebra $C(X)$ of real valued continuous functions on $X$, we denote

(3.3) $Z(I) = \{Z(f) \mid f \in I\}$

This is known to be a $z$-filter on $X$.

Further, for every $z$-filter $F$ on $X$, we denote

(3.4) $I(F) = \{f \in C(X) \mid Z(f) \in F\}$

This is known to be an ideal in $C(X)$. Furthermore
(3.5) \( Z(I(F)) = F, \quad I(Z(I)) \supseteq I \)

**Sets and Ideals.** With the above customary notations, and based on (2.2), for any ideal \( I \) in the algebra \( C(X) \) of real valued continuous functions on \( X \), we denote

(3.6) \( P(I) = \{ p \in \beta X \mid I \subseteq M^p \} \subseteq \beta X \)

Clearly \( P(I) \neq \emptyset \), since every ideal \( I \) in \( C(X) \) is contained in some maximal ideal \( M^p \) in \( C(X) \). Also obviously

(3.7) \( I \subseteq \bigcap_{p \in P(I)} M^p \)

however, equality need not always hold. Indeed, let \( X = [-1, 1] \subseteq \mathbb{R} \), and \( I \) be the principal ideal in \( C(X) \) generated by the function \( id_X \), that is

\[
I = \{ f \in C(X) \mid \exists g \in C(X) : f(x) = xg(x), \ x \in X \}
\]

In this case \( P(I) = \{0\} \), while \( I \neq M^0 \), since if we define \( f \in C(X) \) by \( f(x) = \sqrt{|x|} \), for \( x \in X \), then \( f \in M^0 \), but \( f \notin I \).

Further, (3.6) and (2.2) give

(3.8) \( P(I) \subseteq \bigcap_{f \in I} \text{cl}_{\beta X} Z(f) \)

Based on the above, and as an extension of (2.2), for every subset \( A \subseteq \beta X \), let us define the ideal in \( C(X) \) given by

(3.9) \( I^A = \bigcap_{p \in A} M^p \)

Then obviously \( I^A = M^p \), for \( A = \{ p \} \), with \( p \in \beta X \). Further, we have

(3.10) \( A \subseteq P(I^A) \) for \( A \subseteq \beta X \)

Also

(3.11) \( I^A = \{ f \in C(X) \mid A \subseteq \text{cl}_{\beta X} Z(f) \} \)

and

(3.12) \( I \subseteq I^{P(I)} \)

**The Problem in Section 1.** In that case we have \( X = \Lambda \times \mathbb{R}^n \), thus we obtain

(3.13) \( Z(u(\psi)) = \Lambda \times Z(\psi) \) for \( \psi \in C(X) \)

where \( Z \) in the left hand term is considered in \( X = \Lambda \times \mathbb{R}^n \), while \( Z \) in the right
hand term is defined in \( \mathbb{R}^n \).

Now for convenience, let us first consider the following particular case of the problem in section 1, namely:

Which are the subsets \( A \subseteq \beta X \), such that

\[
\mathcal{I}^A \cap \mathcal{U}_A(\mathbb{R}^n) = \{ 0 \} \quad ?
\]

In other words, which are the subsets \( A \subseteq \beta X \), such that, given any \( \psi \in C(\mathbb{R}^n) \), we have

\[
u(\psi) \in \mathcal{I}^A \implies \psi = 0 \quad \text{on} \quad \mathbb{R}^n \quad ?
\]

In view of (3.11), (3.13), the problem (3.15) is equivalent with finding the subsets \( A \subseteq \beta X \), such that, given any \( \psi \in C(\mathbb{R}^n) \), we have

\[
A \subseteq \text{cl}_{\beta(\Lambda \times \mathbb{R}^n)}(\Lambda \times Z(\psi)) \implies \psi = 0 \quad \text{on} \quad \mathbb{R}^n
\]

Clearly, the larger \( A \), the more likely that \( Z(\psi) \) is large, thus the implication in (3.16) may hold. An obvious sufficient condition for (3.16) is the following

\[
pr_{\mathbb{R}^n}(A \cap (\Lambda \times \mathbb{R}^n)) \text{ dense in } \mathbb{R}^n
\]

**The Case of Space-Time Foam Ideals.** Let us note here what happens in the case of sequences of continuous functions, see (2.11), (2.12)

\[
w = (w_\lambda \mid \lambda \in \Lambda) \in \mathcal{J}_L, \Sigma(\mathbb{R}^n)
\]

where \( \Sigma \subset \mathbb{R}^n \) is such that \( \mathbb{R}^n \setminus \Sigma \) is dense in \( \mathbb{R}^n \). In view of (2.12), we have

\[
Z(w) = \bigcup_{\lambda \in \mathbb{R}^n \setminus \Sigma} (\{ \lambda \} \times \{ x \}) \subseteq \Lambda \times \mathbb{R}^n = X
\]

where \( \lambda_x \in \Lambda \) and \( \{ \lambda \} = \{ \mu \in \Lambda \mid \mu \geq \lambda_x \} \).

Obviously, for the set \( A = Z(w) \) in (3.19), we have

\[
A \text{ satisfies } (3.17) \iff \mathbb{R}^n \setminus \Sigma \text{ dense in } \mathbb{R}^n
\]

which clarifies the conditions in (2.5) and (2.9).

### 4. On the Off Diagonality Condition

In Rosinger [6, chap. 3, pp. 65-119] was for the first time given an algebraic characterization of all differential algebras \( A \) of generalized functions which contain the Schwartz distributions \( \mathcal{D}' \). Based on this characterization, the infinite class of all dif-
ferential algebras of generalized functions containing the Schwartz distributions was constructed in Rosinger [6], see also Rosinger [1-5,7-19].

These differential algebras prove to be of particular interest in the solution of large classes of nonlinear PDEs, see Rosinger [1-19], Rosinger & Walus [1,2], Colombeau, Biagioni, Oberguggenberger, Grosser et.al., and the literature cited there, as well as the subject 46F30 in the AMS Subject Classification, at www.ams.org/msc/46Fxx.html

Recently, a class of these differential algebras, called space-time foam algebras was introduced in Rosinger [12-16]. This class proves to be of special interest in setting up a Differential Geometry which can handle the largest classes of singularities so far in the literature. This property is of special interest in General Relativity and Quantum Gravity, see Mallios & Rosinger [1-3] and Mallios [1,2].

Returning to the mentioned algebraic characterization, it also shows that the Colombeau algebras, see Colombeau, Biagioni, Oberguggenberger, are a particular case of the infinite class of differential algebras constructed in Rosinger [1-19], see also the comment in Grosser et.al. [p. 7].

In some more detail the situation is as follows. The differential algebras $A$ of generalized functions in the mentioned infinite class are of the quotient form

\[(4.1) \quad A = A/I\]

where

\[(4.2) \quad I \subset A \subseteq (C^\infty(\mathbb{R}^n))^\Lambda\]

with $\Lambda$ being suitable infinite sets, while $A$ are subalgebras in $(C^\infty(\mathbb{R}^n))^\Lambda$, and $I$ are ideals in $A$.

In this case, the off diagonality condition which characterizes such quotient algebras $A$ when $A = (C^\infty(\mathbb{R}^n))^\Lambda$, is given by

\[(4.3) \quad I \cap U^\Lambda_N(\mathbb{R}^n) = \{0\}\]

where $U^\Lambda_N(\mathbb{R}^n)$ is the diagonal in the Cartesian product $(C^\infty(\mathbb{R}^n))^\Lambda$.

However, at a first approach, one may set aside the $C^\infty$-smoothness involved in (4.1) - (4.3), and instead, consider the more general and merely continuous setup presented in section 1.
